ScamScan

Scam-message intelligence for mobile-money markets.

THE PROBLEM

Fraud now arrives as a **message**.

SMS & mobile money

A fake M-Pesa / MoMo alert asks for a PIN or an OTP. The money moves in seconds, and rarely comes back.

The wallet is the account

In low-resource markets a mobile wallet holds the savings. A drained wallet is not an inconvenience.

Filters miss it

Generic spam filters learn from Western email. Code-mixed, region-specific scams slip straight through.

THE SOLUTION

It doesn't just flag a scam. It tells you **what to do.**

ScamScan reads the message text alone, then turns the verdict into action. That action layer is the differentiator.

01 — READ

The risk

A calibrated verdict across four fraud classes, with a colour-coded risk level and a plain-language read of what the message wants.

TAXONOMY

One verdict, four classes.

■ Phishing

Credential and link harvesting that impersonates a bank, telecom or service.

THE APPROACH

From corpus to live verdict.

A deliberately classical pipeline: interpretable, robust on a small corpus, and cheap to serve.

RESULTS

Measured, not claimed.

BEATS RANDOM FOREST

LIVE DEMO

Paste a message. Get a verdict in a second.

A real request hits the hosted model, returns the class and confidence, then the risk, the steps, and the contacts.

FUTURE WORK

Where it goes next.

A language-model arm

Benchmark an LLM against the classical baseline: accuracy vs cost vs latency.

THANK YOU

Read a message.
Know its intent.
